TLib: A Flexible C++ Tensor Framework for Numerical Tensor Calculus

CEM BASSOY, Fraunhofer Institute of Optics, System Technologies and Image Exploitation, Germany

Numerical tensor calculus comprises basic tensor operations such as the entrywise addition and contraction of higher-order tensors. We present TLib, a flexible tensor framework with generic tensor functions and tensor classes that assists users to implement generic and flexible tensor algorithms in C++. The number of dimensions, the extents of the dimensions of the tensors and the contraction modes of the tensor operations can be runtime variable. Our framework provides tensor classes that simplify the management of multidimensional data and utilization of tensor operations using object-oriented and generic programming techniques. Additional stream classes help the user to verify and compare of numerical results with MATLAB. Tensor operations are implemented with generic tensor functions and in terms of multidimensional iterator types only, decoupling data storage representation and computation. The user can combine tensor functions with different tensor types and extend the framework without further modification of the classes or functions. We discuss the design and implementation of the framework and demonstrate its usage with examples that have been discussed in the literature.

1 INTRODUCTION

In modern mathematics a higher-order tensor is defined as an element of a tensor product space [de Silva and Michalek 2012; Lim 2012]. Higher-order tensors are coordinate-free in an abstract fashion without choosing a basis of the tensor product space. In the realm of numerical tensor calculus, higher-order tensors with a coordinate representation are considered [Hackbusch 2014; Lim 2012]. The bases are chosen implicitly, and the values of some measurements are then recorded in the form of a multidimensional array. We define a multidimensional array as an entity that holds a set of data of the same type whose elements are arranged in a rectangular pattern. In some cases higher-order tensors are referred to as hypermatrices, N -way arrays or N -dimensional table of values [Cichocki et al. 2009; Lathauwer et al. 2006a; Lim 2012] where N is order, i.e. the number of dimensions.

Basic tensor operations are the tensor-tensor, tensor-matrix, tensor-vector multiplication, the inner and outer product of two tensors, the Kronecker, Hadamard and Khatri-Rao product [Cichocki et al. 2009; Lim 2012]. Common methods utilizing tensor operations are e.g. the higher order decompositions or to calculate the eigenvalues or singular values of a higher-order tensor [Cui et al. 2014; Kolda and Bader 2009; Lathauwer et al. 2006a; Ng et al. 2009]. Other types of tensor decomposition are the CP (Canonical Decomposition/Parrallel Factor Analysis) [Faber et al. 2003; Harshman and Lim 1994] and Tucker Decomposition [Lim and Choi 2007; Tucker 1966] which are mainly used within the field of psychometrics and chemometrics. Other areas of application are signal processing [Friedland et al. 2005; Sava and Eldén 2007], computer graphics [Suter et al. 2013; Vaidya and Terzopoulos 2002] and data mining [Kolda and Sun 2008; Rendle et al. 2009].

ON SOME PROBLEMS OF TENSOR CALCULUS. I

ABSTRACT. Basic definitions of linear algebra and functional analysis are given. In particular, the definitions of a semigroup, group, ring, field, module, and linear space are given [1–3, 6]. A local theorem on the existence of homeomorphisms is stated. Definitions of the inner r -product, local inner product of tensors whose rank is not less than r , and of local norm of a tensor [22] are also given. Definitions are given and basic theorems and propositions are stated and proved concerning the linear dependence and independence of a system of tensors of any rank. Moreover, definitions and proofs of some theorems connected with orthogonal and biorthonormal tensor systems are given. The definition of a multiplicative basis (multibasis) is given and ways of construction bases of modules using bases of modules of smaller dimensions. In this connection, several theorems are stated and proved. Tensor modules of even orders and problems on finding eigenvalues and eigentensors of any even rank are studied in more detail than in [22]. Canonical representations of a tensor of any even rank are given. It is worth while to note that it was studied by the Soviet scientist I. N. Vekua, and an analogous problem for the elasticity modulus tensor was considered by the Polish scientist Ya. Rikhsievskii in 1983–1984.

1. Basic Notions and Definitions from Linear Algebra and Functional Analysis

We give basic notions and definitions from linear algebra and functional analysis [1–3, 5, 6, 13, 16, 22].

Definition 1.1. A *semigroup* is a set where the operation is defined which associates any ordered pair of elements with the third element, the result of the operation. The operation is assumed to be associative. The set of nonnegative integers with respect to the addition and the same set with respect to the multiplication is a semigroup.

Definition 1.2. A semigroup is called the *group* if there exists a neutral element e in it such that for all a from the group $a * e = a = e * a$ (we denote by $*$ the action), and for each element a , there exists an inverse element a^{-1} such that $a * a^{-1} = e$. The following are examples of groups: the set of all integers with respect to the addition, the set of positive rational numbers with respect to the addition. These groups are commutative. Commutative groups are also called Abelian groups.

The action in the group is usually denoted by the multiplication (a multiplicative group) and sometimes by the addition (an additive group). The addition action is used only for Abelian groups. The neutral element in a multiplicative group is denoted by 1 and in an additive group it is denoted

Abstract: In this paper, we investigate and discuss in detail the structures of quaternion tensor SVD, quaternion tensor rank decomposition, and a Hermitian quaternion tensor decomposition with the tensorable group structure and Einstein product. Then we give the expression of the Moore-Penrose inverse of a quaternion tensor by using the quaternion tensor SVD. Moreover, we consider a generalized Sylvester quaternion tensor equation. We give some necessary and sufficient conditions for the existence of a solution to the generalized Sylvester quaternion tensor equation in terms of the Moore-Penrose inverses of the quaternion tensors. We also present the expression of the general solution to this tensor equation when it is solvable. As applications of this generalized Sylvester quaternion tensor equation, we derive some necessary and sufficient conditions for the existence of μ -Hermitian solutions to some quaternion tensor equations. We also provide some numerical examples to illustrate our results.

1. Introduction

Decompositions of higher-order tensors have found large applications in signal processing [10, 15, 16, 17, 18, 20, 22, 23, 24, 26, 30], data mining [41, 34, 36, 38], genome signals [1], [42], [45], [42], computer vision [36, 39, 40], higher-order statistics [12, 13, 19], pattern recognition [26, 25], chemometrics [11, 92], graph analysis [36], numerical linear algebra [28, 24, 37], [36], [23], aerospace engineering [24], and electronics. Kolda and Bader [39] provided an overview of the theoretical developments and applications of tensor decompositions in 2009. There have been many papers discussing tensor decompositions and other fields of tensor theory [26-39, 14, 18, 20, 22, 23, 24, 26, 30, 147-152, 160-169, 170, 171].

Tensor equations are found to be useful in engineering and science. For instance, tensor equations can be used to model some problems in continuum physics and engineering, isotropic and anisotropic elasticity [48]. There have been some papers using different approaches to investigate tensor equation over fields [2, 36, 28, 34].
